# 1 Abstract

Subsistence-oriented indigenous communities across Alaska rely heavily on Traditional Ecological Knowledge (TEK), a holistic understanding of their environment acquired through generations of observation and cultural transmission. Among the Anishinaabek tradition, sweet grass symbolizes wisdom and knowledge (Kimmerer, 2020), passed down from elders to younger generations. Indigenous hunters and gatherers have long observed the alignment of grass and plants after the growing season as indicative of prevailing wind directions. Predominant wind direction serves a crucial role to subsistence practitioners when hunting, fishing, settling, and keeping track of changing weather. Due to the remote and harsh conditions, traditional weather stations are absent to measure shifts in historically predominant wind directions. On islands like St. Lawrence Island in Savoonga, AK, natives have observed a shift from historically predominant northerly wind patterns to southerly and easterly and dominated winds. In a previous study Dr. Jon Rosales (Environmental Studies) and his team collected images of grass lay from St. Lawrence University's Living Laboratory and manually attempted to measure grass lay angles and relate them with wind data. This research project seeks to reinforce Traditional Ecological Knowledge (TEK) with Scientific Ecological Knowledge (SEK) to develop our understanding of Alaskan indigenous wisdom and its relation with modern scientific findings. We investigated the Histogram of Oriented Gradients (HOG) algorithm to automate the measurement of grass lay angles. We applied the algorithm to various images sampled from the internet and the Living Laboratory to test its viability.

## 2 Data

To evaluate the algorithm's performance, we collected images with varying levels of complexity. Beginning with basic geometric shapes and diagonal lines sourced from Google Images, we established a foundational data set for initial testing. We incorporated aerial cityscapes including San Francisco, Salt Lake City, and Detroit from Mapbox, aiming to assess the algorithm's ability in identifying urban grid structures such as streets and highways. Additionally, we included images of grass sourced from both Google Images and Dr. Jon Rosales (Environmental Studies) at St. Lawrence University's Living Lab. The images sourced from the Living Laboratory included aerial and close-up shots, with special attention given to aerial images which featured a northern indicator line. To ensure consistent orientation, each aerial image was manually rotated to align north facing direction upwards before analysis, with the northern indicator subsequently removed to avoid introducing artificial lines in the image.

### 3 Methods

The HOG algorithm, introduced by Navneet Dalal and Bill Triggs in 2005 (Dalal & Triggs, 2005), is a popular technique for object detection in images. The algorithm can identify gradient magnitudes and angles at each pixel in an image. The preliminary steps involved using the ‘skimage’ library from Python to preprocess the images of interest. This included loading, resizing, and converting the images to grayscale. Images were rescaled to standardize their resolutions and preserve their aspect ratios to prevent distortion that could affect the accuracy of angle identification. Converting the images to grayscale was necessary because it allowed for focusing on a single channel to represent pixel intensity, rather than three channels (red, green, and blue).

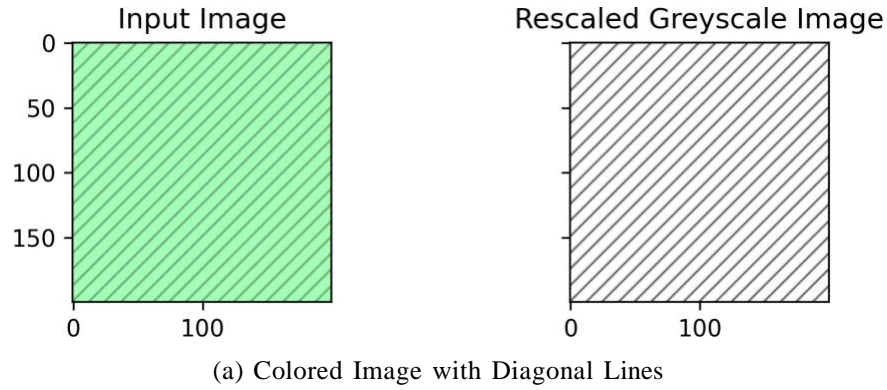

Figure 3.1: Rescaling and Converting Image to Greyscale

The HOG features were then computed for the resized images, which involved calculating the gradient magnitudes and angles at each pixel. The gradient magnitude at each pixel is comprised of the gradients in the ‘x’ and ‘y’ directions. The gradient in the x-direction is computed by subtracting the pixel value to the left of pixel of interest is subtracted from the pixel value to its right. Similarly, the gradient in the y-direction is calculated by pixel value below the pixel of interest is subtracted from the pixel value above the pixel of interest.

$$\begin{aligned}G_x &= I(r, c + 1) - I(r, c - 1) \\G_y &= I(r + 1, c) - I(r - 1, c)\end{aligned}$$

Now to calculate the gradient magnitude at the pixel of interest, the Pythagorean Theorem can be utilized where the gradient magnitude is equal to the square root of the x-gradient squared plus the y-gradient squared. The angle at a given pixel can be calculated by taking the inverse tangent of its y-gradient divided by its x-gradient. It is important to note all angles produced by this algorithm are between zero and one hundred eighty degrees. This occurs, because the inverse tangent function used for calculating a given pixel's angle cannot distinguish between all four quadrants.

$$Magnitude(\mu) = \sqrt{G_x^2 + G_y^2}$$

$$Angle(\Theta) = \tan^{-1}\left(\frac{G_x}{G_y}\right)$$

a) Gradient Magnitudes of Diagonal Lines Image

Figure 3.2: Plotting Gradient Magnitudes as Image

Next, histograms are constructed to visualize the distribution of gradient magnitudes and angles. Two different techniques for creating gradient angle histograms were implemented. The first histogram was created by counting the number of angles that fell into their respective bins. The second scheme factors in a pixel's gradient magnitude and its allocation to its bordering bins. Here, the weight assigned to each bin is calculated by the angle's deviation from the center of its central bin. This approach allows for a more representative histogram which splits angles between bins and takes their magnitudes into account. Lastly, these histograms are converted to polar histograms so the primary angles can be visualized and compared to their original images.

# **I**

## **Results**

## 4 Aerial Cityscapes

### 4.1 Motivation

Download aerial cityscape images from Mapbox's API of San Francisco, Salt Lake City, and Detroit to determine if the HOG algorithm is capable of identifying dominant angles of each city's grid layout.

### 4.2 Load R Packages and Python Libraries

```
# Load R Packages
library(reticulate)
library(tidyverse)
library(mapsapi)
library(mapboxapi)
library(magick)
```

```
# Load Python Libraries
import matplotlib.pyplot as plt
import pandas as pd
from skimage.io import imread, imshow
from skimage.transform import resize
from skimage.feature import hog
from skimage import data, exposure
import matplotlib.pyplot as plt
from skimage import io
from skimage import color
from skimage.transform import resize
import math
from skimage.feature import hog
import numpy as np
```

### 4.3 Download Aerial City Images from Mapbox

```
# Get Mapbox token from System Environment
key <- Sys.getenv("mapbox_key")
```

```
# Download map of San Francisco, CA
map <- static_mapbox(
  access_token = key,
  style_url = "mapbox://styles/mapbox/satellite-v9",
  width = 300,
  height = 200,
  image = T, latitude = 37.792004, longitude = -122.428079, zoom = 12
)

magick::image_write(map, "images/san_francisco_scale_zoom_12.png")
```

```
# Download map of Salt Lake City, UT
points_of_interest <- tibble::tibble(
  longitude = c(-112.065945, -111.853948,
               -111.852956, -112.023371),

  latitude = c(40.794275, 40.791516,
               40.502308, 40.502308)
)

prepped_pois <- prep_overlay_markers(
  data = points_of_interest,
  marker_type = "pin-l",
  label = 1:4,
  color = "#fff",
)

map <- static_mapbox(
  access_token = key,
  style_url = "mapbox://styles/mapbox/satellite-v9",
  width = 800,
  height = 1200,
  image = T,
  latitude = 40.7,
  longitude = -111.876183, zoom = 12
)
```

```
magick::image_write(map, "images/salt_lake_city_zoom_12.png")
```

```
# Download map of Detroit, MI
map <- static_mapbox(
  access_token = key,
  style_url = "mapbox://styles/mapbox/satellite-v9",
  width = 1200,
  height = 800,
  image = T,
  latitude = 42.336322,
  longitude = -83.048705, zoom = 12
)

magick::image_write(map, "images/detroit_zoom_12.png")
```

(a) San Francisco, CA

(b) Salt Lake City, UT

(c) Detroit, MI

Figure 4.21: Polar Plots using Distributed Binning Technique for Aerial Cityscapes

## 4.12 Discussion

The San Francisco image delivered the most promising results due to its closer zoom level compared to the Salt Lake City and Detroit images. Angles in the seventy-degree range emerged as the most frequent, accurately reflecting the slightly diagonal west-east streets of downtown San Francisco. The layout of Salt Lake City significantly influenced the results of its polar plot. With its narrow vertical grid layout, the city exhibited a higher frequency of vertical angles and a smaller yet significant occurrence of horizontal gradient angles. For the images of San Francisco and Detroit, the outcomes between the Standard and Distributed binning techniques exhibited similar results. However, for Salt Lake City, the Distributed technique notably favored a higher frequency of both vertical and horizontal angles.

## 5 Grass Images

### 5.1 Motivation

Use images from the internet and St. Lawrence University's Living Laboratory to determine if the HOG algorithm can identify dominant angles of grass lay.

### 5.2 Input Images

(a) Internet Grass Image

(b) Living Lab Aerial Image

(c) Living Lab Close-Up Image

Figure 5.3: Input Grass Images

### 5.3 Load R Packages and Python Libraries

```
# Load R Packages
library(reticulate)
library(tidyverse)
library(mapsapi)
library(mapboxapi)
library(magick)
```

```
# Load Python Libraries
import matplotlib.pyplot as plt
import pandas as pd
from skimage.io import imread, imshow
from skimage.transform import resize
from skimage.feature import hog
from skimage import data, exposure
import matplotlib.pyplot as plt
from skimage import io
from skimage import color
from skimage.transform import resize
import math
from skimage.feature import hog
import numpy as np
```

## 5.4 Collect HOG Features for Grass Images

```
# List for storing images
img_list = []

# Internet Grass Image
img_list.append(color.rgb2gray(io.imread("images/grass_image2.jpg")))

# Living Lab Rotated Aerial Grass
img_list.append(
    color.rgb2gray(
        io.imread("images/living_lab_aerial/aerial_grass_living_lab_rotated.jpg")))

# Living Lab Grass Close-up
img_list.append(
    color.rgb2gray(
        io.imread("images/living_lab_aerial/LL_zoomed_in_12.jpg")
    )
)

(a) Internet Grass Image

(b) Aerial Living Lab Image

(c) Close-Up Living Lab Image

Figure 5.21: Polar Plots using Distributed Binning Technique for Grass Images

## 5.12 Discussion

The internet grass image was selected for its simplicity and general diagonal direction. Both techniques proved quite successful at identifying the image's predominate diagonal gradient angles. The aerial image from the Living Laboratory posed a greater challenge due to its wider zoom range, causing a higher degree of variability in grass lay direction. Ultimately, the standard binning technique was able to identify this north-eastern trend seen on the right side of the image, while the distributed method identified a slightly more eastern trend. Lastly, the north-eastern trend in close-up image from the Living Laboratory was successfully identified in both the standard and distributed methods of binning.

## 6 Backflip Image

### 6.1 Motivation

Test the HOG algorithm's ability to identify dominant edges using an image of a skier. This scenario adds complexity with both a skier in the foreground and a crowd in the background, allowing us to observe how the algorithm deals with additional “noise”.

### 6.2 Input Image

(a) Skiing Backflip Image

Figure 6.1: Input Image

## 6.3 Load R Packages and Python Libraries

```
# Load R Packages
library(reticulate)

(a) Polar Plot Using Standard HOG Technique (b) Polar Plot Using Distributed HOG Technique

Figure 6.7: Polar Plots using Standard and Distributed Binning Technique for Skiing Backflip Image

## 6.12 Discussion

When looking at the gradient magnitudes in image form the most definitive lines occur where the snow from the jump is visible. This makes sense, because the snowy jump is a uniform white, resulting in minimal gradient magnitudes from one pixel to the next within this area. When the edge of the snow meets the crowd in the background, there is a great increase in gradient magnitude. Since the snowy jump in this image is mostly horizontal with some incline and decline, both polar plots identify the horizontal angle as being the most frequent. Interestingly, the distributed binning technique has a notably smaller frequency of vertical lines, likely due to the greater influence of magnitudes on their contribution to the histogram.

## 7 Conclusion

In this study, the Histogram of Oriented Gradients (HOG) algorithm was utilized to analyze a variety of images, including those sourced from both the internet and St. Lawrence University. Our objective was to extract dominant angles from these images and assess the algorithm's potential for automating the manual grass lay measurement technique performed by Dr. Rosales and his team. Their research focuses on correlating grass lay direction with predominant wind data, locally at St. Lawrence University, to evaluate potential shifts in prevailing Arctic wind patterns observed by indigenous communities. The HOG algorithm was successful in identifying patterns, streets, edges, and grass lay angles from various images. Images with visually dominant angles were evaluated accurately by the algorithm. Even in scenarios where images introduced increased variability, such as the aerial Living Laboratory and skiing image, visual patterns were reflected by the polar histograms.

While the HOG algorithm proved effective, it does come with limitations. Although it can identify the axis of a gradient's angle, it lacks the capability to determine the direction of a gradient's angle. This occurs because the inverse tangent function used to calculate a gradient's angle using the x-gradient and y-gradient components can only produce angles between 0 and 180 degrees. This poses potential challenges when counting angle frequencies, as any angle with a directional component surpassing 180 degrees gets conflated with its corresponding angle below 180 degrees. In order to achieve optimal results, it is best to use images with relatively square aspect ratios, higher zoom levels, and consistent lighting. As seen in the Salt Lake City image, having a predominantly rectangular aspect ratio can accentuate the frequency of angles in a certain direction because they naturally have a higher occurrence. Zoom level played a critical role when analyzing the aerial cityscapes, as San Francisco emerged having the most accurate results with its slightly diagonal grid layout. Lastly, the skiing image highlighted the impact of object brightness on polar plots. Specifically for the distributed binning technique, images featuring brighter objects tended have higher frequencies of corresponding gradient angles because of their increased gradient magnitudes.

In conclusion, our findings visualize the efficacy of the HOG algorithm in extracting gradient angles from various images, particularly lay angles from grass images. To further validate the results from this study, the next step entails a comparison between the results generated by the HOG algorithm's polar plots and the manually measured angles by Dr. Rosales' team. Additionally, future comparison of aerial grass images with corresponding wind data is necessary to apply this methodology on St. Lawrence Island, AK to facilitate more efficient data collection and analysis.
